Slow Display

Problem: A number of users have reported that their display takes 15 seconds or more to fully come on.

Solution: According to Yaesu: The technical explanation is that there is some protection built in to avoid pushing the display to full blast from a very cold start which would result in a shorter life span for the display. It appears to be a normal event for a lot of owners, and as long as the display comes on full power eventually, it is probably "normal".
